

# **ALARO overview of last two years**

**(or ‘more progress in depth  
than speedy advances’)**

*J.-F. Geleyn*

*AIWD, Vienna, Austria, 12-14/05/2014*

## Conclusions (two years ago)

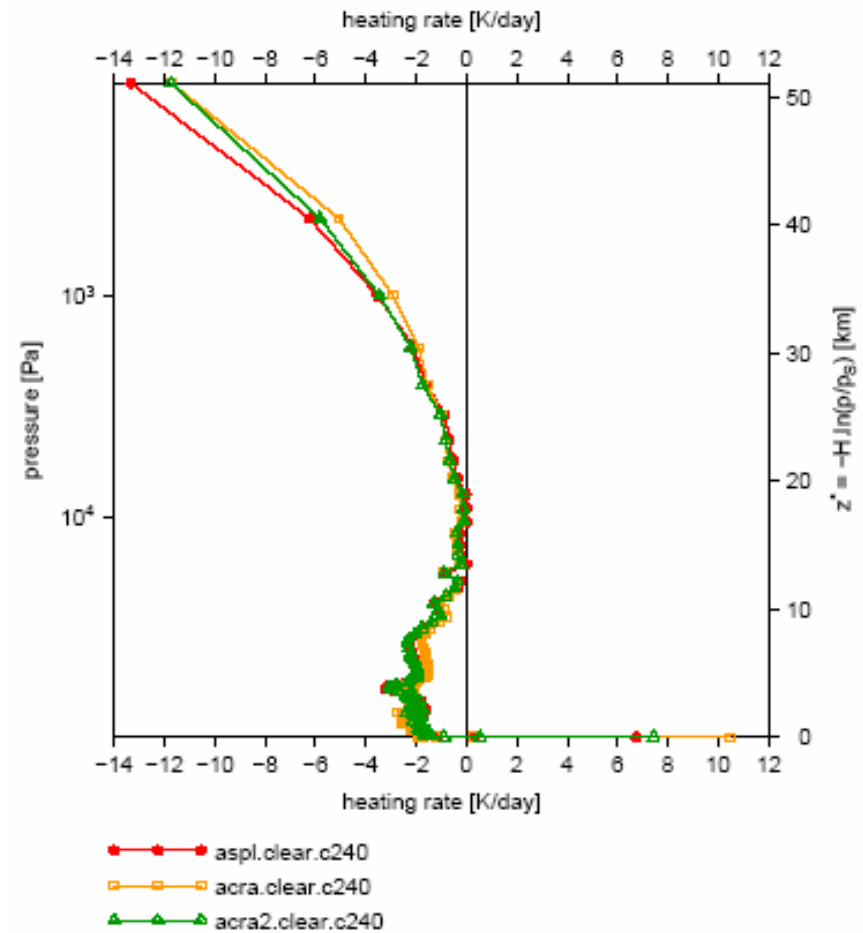

- ALARO-0 was a success in organisation, scientific progress and operational integration (perhaps with a bit of luck for the latter).
- It was logical that ALARO-1 should follow a somewhat different path.
- It might however (we do not know yet) have happened in an exaggerated way.
- In these 2<sup>nd</sup> ALARO-1 Working Days we should thus possibly aim at innovative:
  - Integration and Validation steps;
  - Proposals for extending an already partly existing algorithmic (two level) ‘strategy’;
  - Back-up possibilities.
- But don’t forget to appreciate the quality of the science!

# Chosen targets (two years ago) and brief sketch of what happened

- New gaseous transmission functions for ACRANEB
  - It turned out that the ‘remaining hurdles’ were far more complex to get rid of than anticipated.
  - Furthermore, once we finally got excellent broadband transmissivities, the core validation revealed some compensating errors in ACRANEB. This called for a revision of several aspects of the NER implementation (statistical model and its links with clouds’ influences, Planck function’s weighting, ice-clouds optical properties, Rayleigh scattering, surface albedo, ...).
  - Hence we now have a fully new code, ACRANEB2, with nearly all problems solved!
- TOUCANS fully stabilised set-up
- Unsaturated downdrafts

# Thermal gaseous effects, single grid-point, single time-step

**Narrow Band Model**

**ACRANEB**

**ACRANEB2**

# Thermal and solar radiative effects, 24h integration with clouds and aerosols

RRTM-FMR

ACRANEB

ACRANEB2

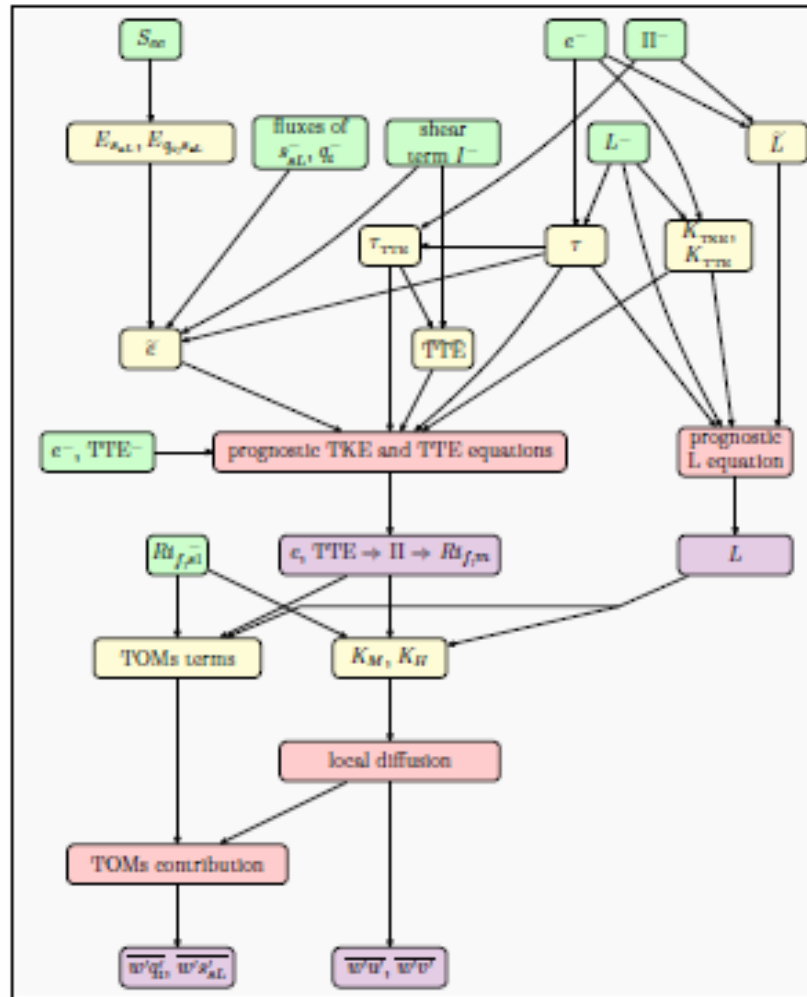

# Chosen targets (two years ago) and brief sketch of what happened

- New gaseous transmission functions for ACRANEB
- TOUCANS fully stabilised set-up
  - In the six months following the Ljubljana A1WD it was realised that the chosen development strategy for TOUCANS was far too ‘open-ended’ (*‘end of the Roman empire’* syndrome => in short, flexibility was more a target for itself than an opportunity to make the whole construction consistent).
  - An in-depth refurbishing took then place on (at least) some three key issues:
    - Prognostic TTE handling;
    - Separated view of heat-related and moisture-related TOMs terms;
    - Shallow convection closure issue and its time-step to time-step handling.
  - Re-creating a consistent picture happened only recently and validation of a safe base-line configuration is just ongoing.
- Unsaturated downdrafts

# TOUCANS time-step organisation (in its most prognostic and complex set-up)

*TOUCANS is now surely more a framework than a scheme, even if being both.*

*The discretisation-solving method and the unifying system for stability dependency functions have been accepted for publication in JAS*

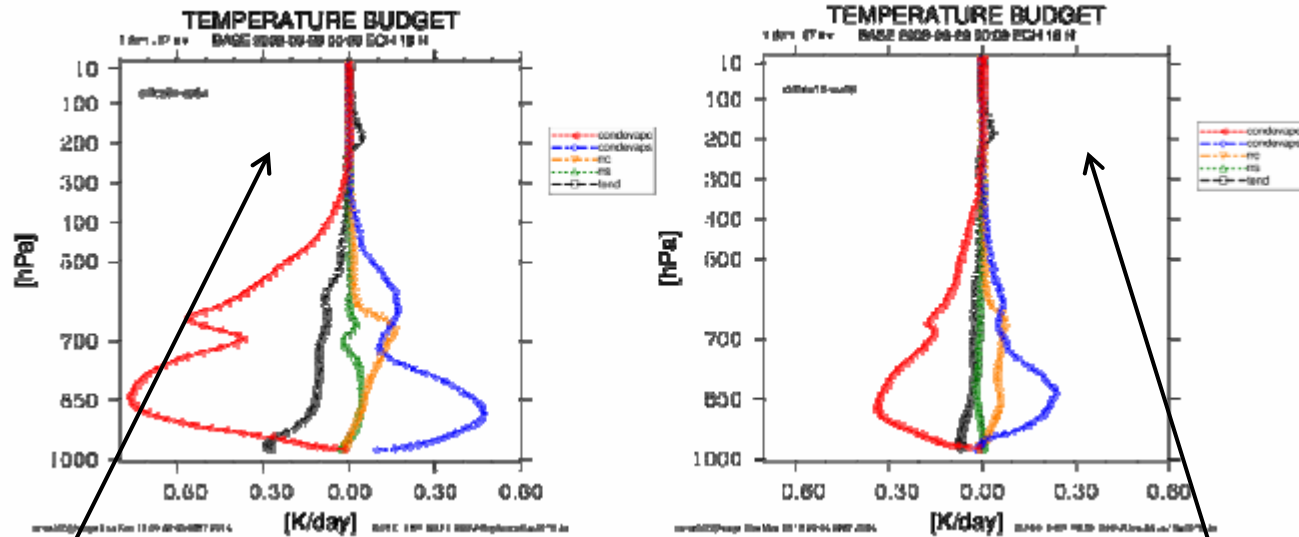

# Chosen targets (two years ago) and brief sketch of what happened

- New gaseous transmission functions for ACRANEB
- TOUCANS fully stabilised set-up
- Unsaturated downdrafts
  - The alternative code to ACMODO (ACNSDO) is now ready for pre-implementation testing, but ...
    - (I) Some modifications to the updraft and microphysics parts seem to be necessary to get a good performance of the new code;
    - (II) There is less possibility to tune the overall intensity of the downdraft's impact (self regulating character of the unsaturated downdrafts formulation).
  - Hence the merge with ACRANEB2 + TOUCANS baseline might be problematic.
  - But a good surprise is not excluded either.

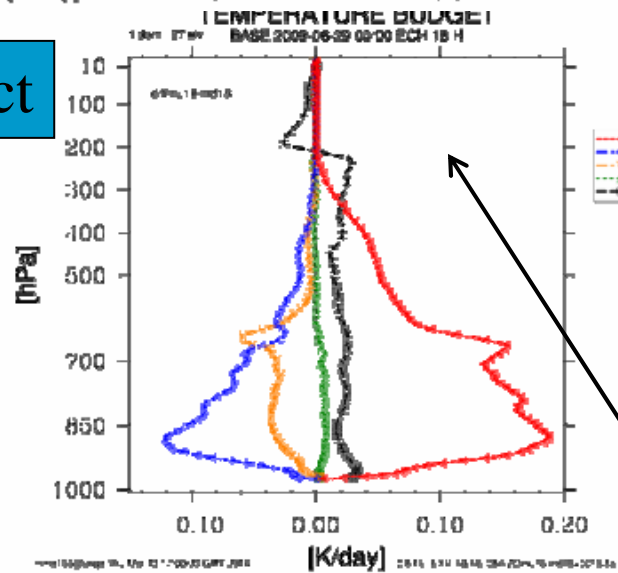

# First results related to unsaturated downdrafts

Present dd's impact

Unsat. dd's impact

**SOME  
TUNING  
NEEDED !!!**

Impact of additional corrections (different scale)

# Validation (present situation)

- *ALARO-0 baseline, plus the closure and entrainment specification modifications, plus ACRANEB2 'as is', plus some minor associated re-tunings were used to search for a 'safe' starting point inside the huge amount of possible TOUCANS configurations.*
- **What was judged already 'OK':**
  - The MY-type tuned CCH02 'Model II' for the stability dependency;
  - The new TOMs formulation (separated heat and moisture equations -with explicit cross terms-; logical extension of the CCH07 equations to the moist case; ...);
  - The turbulent transport of condensates;
  - The computation of the energy source-terms from past-time step values of fluxes (and wind shear terms);
  - The new formulation for the shallow convection closure.

# Validation (present situation)

- *ALARO-0 baseline, plus the closure and entrainment specification modifications, plus ACRANEB2 'as is', plus some minor associated re-tunings were used to search for a 'safe' starting point inside the huge amount of possible TOUCANS configurations.*
- What is probably 'OK' (but not yet fully validated):
  - The prognostic treatment of TTE.
- What surely needs further efforts:
  - The hybrid configuration for using specific moist entropy as a marker of anisotropy-related stability aspects;
  - The whole problem of the interactivity for the length scale  $L$  (specification with respect to TKE, prognostic handling, moisture influenced computation).

# Some (first) validation results: 'safe' configuration vs. ALARO-0

Summer – 11 days

Winter – 10 days

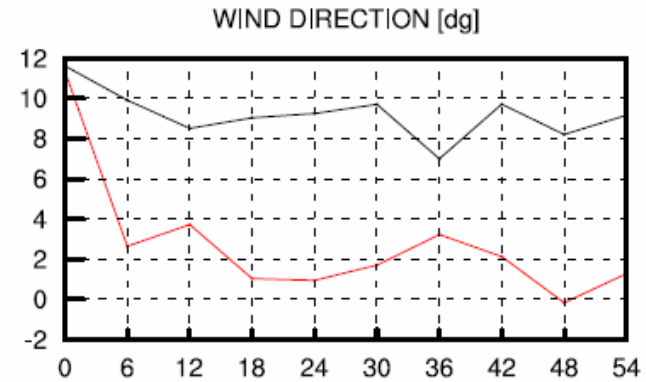

— ref  
— test

# Conclusions (now)

- The past two years showed a lot of progress, but not of the type expected in Ljubljana ...
- We believe to be quite safe with what ACRANEB2 brings in.
- For TOUCANS the situation is topic-dependent (or sometimes even sub-topic-dependent), which is at the same time worrying and promising.
- For unsaturated downdrafts we do not know yet, alas.
- We have a quasi-neutral intermediate baseline capitalising on the best of ACRANEB2 and TOUCANS.
- We spoke here only about NWP-type development (climate downscaling also brought in very good news).
- **We miss a structure in which developers can get some help during validation for integration phases (after that it is a bit late, for all sides ...).**
